# Light in web

light - Google-Suche

https://www.google.fr/search?q=light&ie=utf-8&...

The screenshot shows a Google search interface in French. At the top, there's a navigation bar with links like '+Ich', 'Suche', 'Bilder', 'Maps', 'Play', 'YouTube', 'Gmail', 'Drive', 'Kalender', 'Übersetzer', and 'Mehr'. Below this is the Google logo and a search bar containing the word 'light'. To the right of the search bar is a blue search button and a red 'ANMELDEN' button. Below the search bar, there's a row of tabs: 'Web' (highlighted with a red box), 'Bilder', 'Maps', 'Shopping', 'News', 'Mehr', and 'Suchoptionen'. Below the 'Web' tab, a red box highlights the text 'Ungefähr 1.800.000.000 Ergebnisse (0,22 Sekunden)'. Below this, there's a cookie notice: 'Cookies helfen uns bei der Bereitstellung unserer Dienste. Durch die Nutzung unserer Dienste erklären Sie sich damit einverstanden, dass wir Cookies setzen.' with 'OK' and 'Weitere Informationen' buttons. The first search result is 'Light - Wikipedia, the free encyclopedia' with a link to 'en.wikipedia.org/wiki/Light' and a 'Diese Seite übersetzen' button. The snippet for this result reads: 'Visible **light** (commonly referred to simply as **light**) is electromagnetic radiation that is visible to the human eye, and is responsible for the sense of sight. Visible ...'. Below this is another result: 'Speed of light - List of light sources - Light (disambiguation) - Light beam'. The second result is 'Light Board Corp: Home' with a link to 'www.lightboardcorp.com/' and a snippet: 'Keine anderen Städte in Deutschland genießen urbanes Surfen und Skaten so sehr wie Hamburg, Köln und München. Um das zu erhalten und Brettsportlern ...'.

# The most complex light sensors: eyes

These seemingly best-known imaging light sensors measure colour in the a relatively wide band (400 – 700 nm) as well as the light intensity within a

- dynamic range of 13 orders of magnitude !
- angular resolution  $\sim 1'$  (oculists call it 100 % sight)
- integration time  $\geq 30$  ms,
- threshold value for signals
  - 5-7 green photons (after few hours adaptation in the darkness)
  - 30 photons on average in the dark

A close-up photograph of a person's face, focusing on their eyes. The person has light-colored, possibly green or grey, eyes and is looking slightly upwards and to the right. Their skin is fair and has a soft texture. The background is a solid, vibrant blue. The image is cropped closely around the eyes, with the top and bottom edges of the face visible.

Razmik Mirzoyan: Light Sensors  
for Astro-Particle Physics

# Complex light sensors

# The human way of developing light sensors

- Human eye cannot resolve in time processes that are faster than its light integration time:  $\sim 30\text{ms}$
- Today with sensors we can easily measure processes with a time resolution  $\leq 10^{-12}\text{ s}$  (ps)
- We can measure images with a time resolution of  $\sim 250\text{ps}$  (gated image intensifiers)
- We cannot cover with a single sensor the dynamic range of a human eye of  $\sim 10^{13}$  (logarithmic) but, for example, the linear dynamic range of a PIN diode could be as high as  $\sim 10^8$

# What LLL sensor can we dream about ?

- Die eierlegende Woll-Milch-Sau (german)  
(approximate english translation: all-in-one device suitable for every purpose)

# What LLL sensor can we dream about ?

- Nearly 100 % QE and photon detection efficiency (PDE)
- Could be made in very large and in very small sizes
- Few ps fast (in air and in many materials the light speed is usually 20-30 cm/ns; in 5 ps it will make 1-1.5 mm)
- Signal amplification  $\times 10^6$
- Noiseless amplification: F-factor - 1.001
- Few % amplitude resolution
- No fatigue, no degradation in lifetime
- Low power consumption
- Operation at ambient temperatures
- No danger to expose to light
- Insensitive to magnetic fields
- No vacuum, no HV, lightweight,...

# Light conversion into a measurable

- Visible light can react and become measurable by:
  - Eye (*human:  $QE \sim 3\%$  & animal*), plants, paints,...
  - Photoemulsion ( $QE \sim 0.1 - 1\%$ ) (photo-chemical)
  - Photodiodes (photoelectrical, evacuated)
    - Classical & hybrid photomultipliers ( $QE \sim 25\%$ )
    - $QE \sim 55\%$  (HPD with GaAsP photocathode)
  - Photodiodes ( $QE \sim 70 - 80\%$ ) (photoelectrical)
    - PIN diodes, Avalanche diodes, SiPM,...
    - photodiode arrays like CCD, CMOS cameras,...

# The „zoo“ of LLL sensors

Kashiwa, Japan

Razmik Mirzoyan: Light Sensors  
for Astro-Particle Physics

# Light in Astro-Physics

- Air-Cherenkov experiments in Astro-physics use Cherenkov light emission in atmosphere
- Milagro, HAWC were/are using Cherenkov emission in water
- Neutrino experiments use Cherenkov light emission in ice (BAIKAL, AMANDA, IceCube), in water (Antares, NESTOR, Kamiokande,...)
- Air fluorescence detectors use fluorescent light emission in atmosphere (High-Res Fly's Eye, AUGER)
- Many experiments, also in high energy physics, use light emission in scintillating solid materials and liquids

## Cherenkov Effect

Medium, refractive index  $n$

Charged particle with  $v < c/n$   
traverses medium  
==> local, shorttime  
polarization of medium

Reorientation of electric  
dipoles results in (very faint)  
isotropic radiation

## Cherenkov Effect

$v < c/n$

==> radiation from different points along the  
trajectory arrive **in phase** within narrow  
light-cone at the observer ==> **bright light**

Similar to sonic boom if  $v > c_{acoustic}$

- Pavel Cherenkov had to spend >1-1,5 hours in a dark, cold cellar, for accomodating his eyes to darkness for seeng the very faint bluish emission from solvents containing radioactive salts
- 1934-1938 conducted a series of brilliant expeirments.
- Obtained Nobel Prize in 1956 for the discovery

# The Beginning of the PMT

# Razmik Mirzoyan: Light Sensors for Astro-Particle Physics

# Quantum Efficiency

Quantum efficiency (QE) of a sensor is defined as the ratio

$$QE = N(\text{ph.e.}) / N(\text{photons})$$

Conversion of a photon into ph.e. is a purely binomial process (and not poisson !)

Light sources of thermal origin can be described by the poisson distribution (including LED)

# Differences between binomial and poisson distributions

SNR = 3.16

mean/ $\sigma$  = 2.24

# Why do we want high Quantum Efficiency

Assume N photons are impinging onto a sensor and every photon has the same probability P to kick out a ph.e..

Then the mean number of ph.e.s is  $N \times P$  and the Variance is equal to  $N \times P \times (1 - P)$

$$\text{Signal/Noise} = \text{mean/sigma} = \frac{N \times P}{\sqrt{[N \times P \times (1 - P)]}} = \sqrt{[N \times P / (1 - P)]}$$

# Signal to noise ratio

The signal-to noise ratio of a light sensor can be calculated as

$$\text{SNR} = [N \times P / (1 - P)]^{1/2}$$

For example, if  $N = 1$  (single impinging photon):

P	0.1	0.3	0.9
SNR	0.33	0.65	3

# Signal to noise ratio

$$\text{SNR} = [N \times P / (1 - P)]^{1/2}$$

For  $N = 20$  impinging photons:

P	0.1	0.3	0.9
SNR	1.5	2.9	13.4

# One of the best known light sensors: the classical PMT

- The impinging photons kick out  $e^-$  from the thin photo cathode ( $\sim 25\text{nm}$ )
- $e^-$  are accelerated in a static electric field ( $\sim 100\text{V}$ ) and hit dynodes arranged in a sequential topology
- Every dynode enhances the number of  $e^-$  by a factor 4-5
- The net gain of a PMT could be  $10^5 - 10^7$
- That allows measuring single photons

# HEGRA Detector, operating 1989 - 2002

Kashiwa, Japan

Razmik Mirzoyan: Light Sensors  
for Astro-Particle Physics

# AIROBICC 8-inch Electron Tubes KB 9352

Development initiated by Eckart Lorenz for the AIROBICC detector of HEGRA

- 8-inch PMTs from Electron Tubes, England
- 6-dynodes, slow ageing
- hemispherical shape
- very fast response, 3-4ns FWHM

# PMTs for MAGIC from Electron Tubes Enterprises and from Hamamatsu

Hamamatsu R10408-01  
ET 9116 A: 1.0 inch  
ET 9117 A: 1.5 inch

- 1-inch were developed initially with ETE (England), initiated by Eckart Lorenz. Then continued with Hamamatsu (Japan). Also Photonis produced a hemispherical PMT for us.
- We used PMTs from ETE in MAGIC-I
- When constructing the MAGIC-II, we checked PMTs from ETE against those from Hamamatsu and finally chose the latter because of higher PDE
- Similarly we co-developed 1.5 PMTs, outer rings of the MAGIC-I camera

# PMTs for MAGIC developed by ETE, Hamamatsu, Photonis

Main advantages offered by 1-inch hemispherical MAGIC-type PMTs:

- ultra-fast response; ETE PMT: rise time 600ps, fall time 700ps, FWHM = 1.2ns
- possible due to 6 dynodes
- hemispherical shape photo cathode
- providing double crossing of photons (the highest probability of the semi-transparent photocathode is ~60% @ 400nm) with light guides
- low gain → slow ageing in time

# Instrumental/technological improvements

Running target: light sensor improvements. Successfully pushing the PDE higher up. Shown for several types of PMTs

- Some 9 years ago we have launched a QE improvement program with manufacturers Hamamatsu (Japan), Photonis (France) and Electron Tubes Enterprises (England).
- The results were very encouraging
- Since about 4 years we launched a new improvement program for CTA PMTs

# Development of PMTs for CTA

Hamamatsu 5 years ago

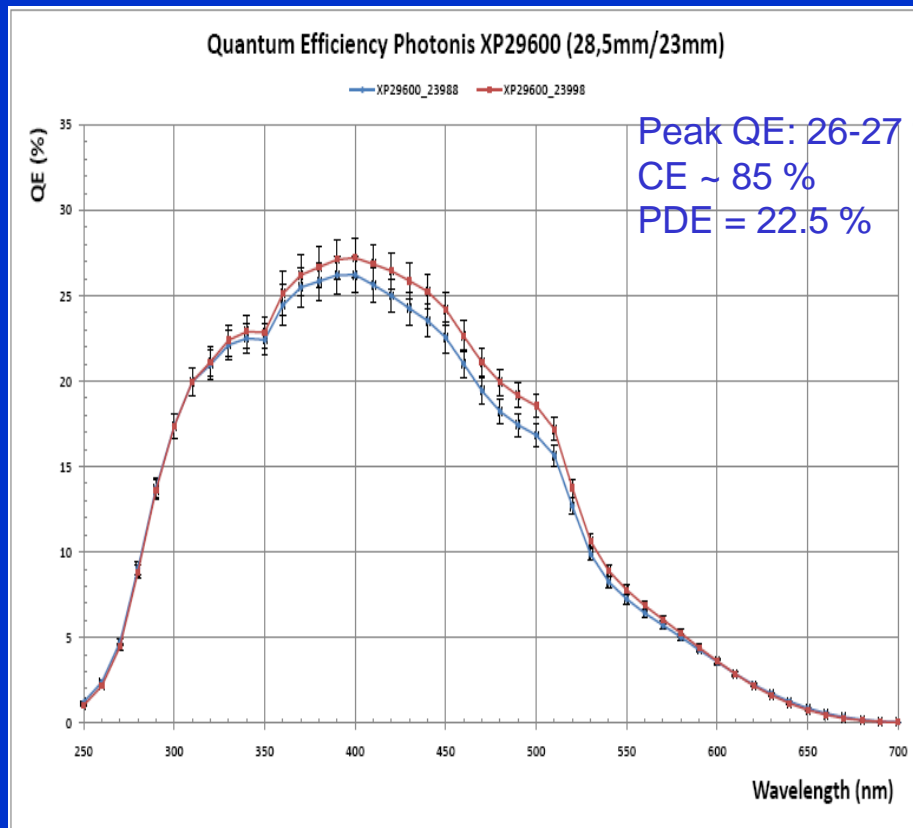

Hamamatsu-CTA PMT today

Electron Tubes Enterprises  
CTA PMT now

# Some background information

- On the left one can see the typical quantum efficiency (QE) of PMTs (from Photonis) used in the H.E.S.S. project
- The peak QE is in the range of 25-27%, CE ~85%
- This was the QE level of PMTs since 1960's

# Some background information

Later on these PMTs have got the name “Superbialkali”

- In 2004-2008 we have developed a program for enhancing the QE, primarily for using in the MAGIC IACTs
- Working with industrial partners *Photonis*, *Electron Tubes* and *Hamamatsu* the QE ofbialkali PMTs was enhanced towards 32-34%
- Note that the collection efficiency of ph.e. was still only ~85%

# Photosensors for CTA

- When the CTA project started the Focal Plane Instrumentation working group asked the consortium for some funds for further development of PMTs
- A very modest level funding became available through the Preparatory Phase funding of CTA
- About 5 years ago we launched a new program for further improving the PMTs
- Today we face an improvement of
  - ph.e. collection efficiency from 85% → 95%, as well as
  - the QE has further increased towards ~40%
  - Afterpulsing level has been reduced from a typical 0.3% → 0.02%

<sup>1</sup>Moscow Engineering Physics Institute, Kashirskoe Shosse 31, 115409 Moscow, Russia

**Abstract:** A Silicon Photomultiplier (SiPM, G-APD) is a novel solid state photodetector which has an outstanding photon counting ability. The device has excellent features such as high quantum efficiency, good charge resolution, fast response (<100 ps), very compact size, high gain (up to  $2 \times 10^6$ ), very low power consumption with low bias voltages (30-70V), immunity to the magnetic field. In the last few years, UV sensitive SiPMs with a p-on-n structure have been developed by a few companies such as Hamamatsu, Photonique, Zecotek Photonics Inc., and institutes such as the MPI-HLL (Max-Planck-Institute for Physics - Max-Planck-Institute Semiconductor Laboratory) as well as the MPI-MEPH (Max-Planck-Institute for Physics - Moscow Engineering Physics Institute) for astroparticle physics applications. Here the current status of the SiPM development in MPI and HLL, MPI and MEPH, and the study of the application to imaging atmospheric Cherenkov telescopes (IACTs) MAGIC/MAGIC-II [1] and CTA [2], and a fluorescence telescope in the space JEM-EUSO [3] will be reported.

**Keywords:** Imaging Cherenkov, Imaging fluorescence, SiPM

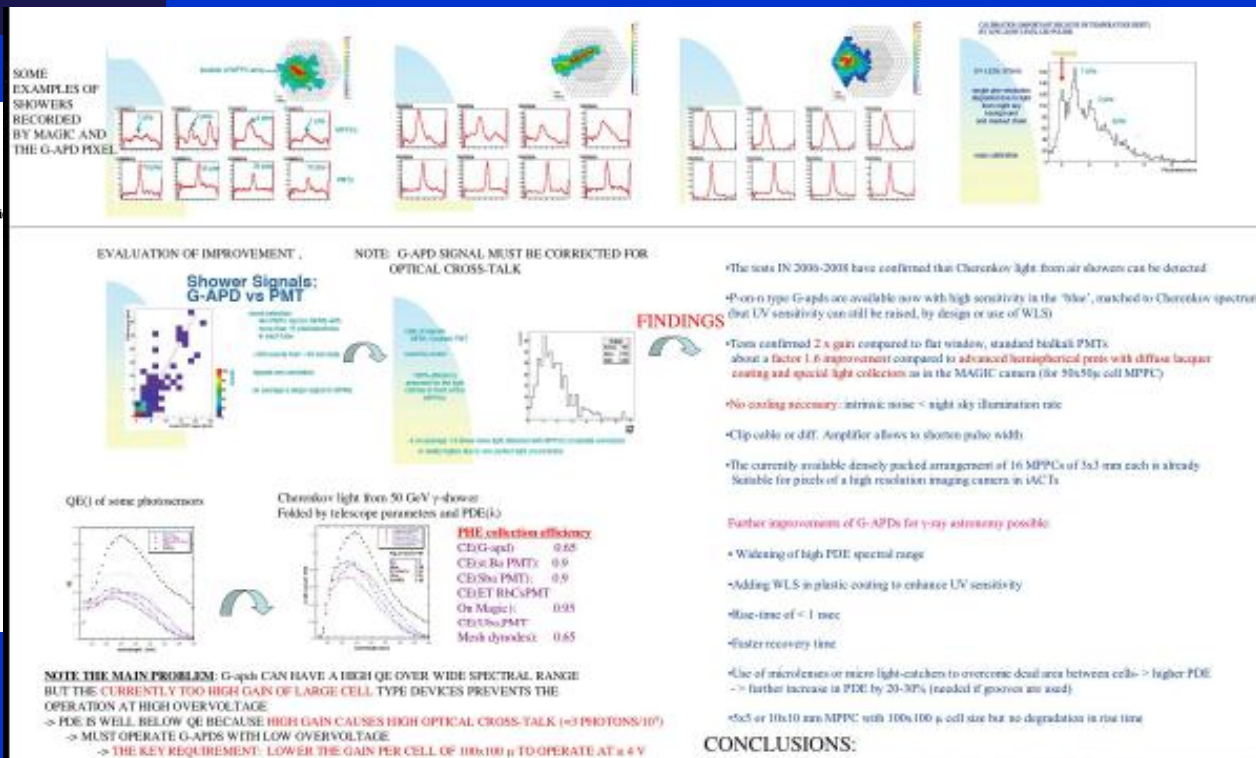

Fig. 1. Top Left/Center: Blue print of 16ch (4x4) of 3x3 mm² MPPC array device (four tracks). Bottom: Photo of 16 ch MPPC array device.

The high PDE of these devices will allow us to lower the threshold energy of gamma ray detection down to 10 - 20 GeV in case of MAGIC telescopes, and ensure the detection efficiency of UHECRs above  $(2-3) \times 10^{19}$  eV

### 1. INTRODUCTION

 Kashiwa, Japan

Razmik Mirzoyan: Light Sensors  
 for Astro-Particle Physics

# 1440-pixel MPPC camera

# FACT telescope camera

## Sensor Plane: Final

# SiPM Essentials

- Photon Detection Efficiency (PDE):

$$\text{PDE}(\lambda) = \text{QE}_{\text{internal}} \times T(\lambda) \times A_{\text{active area}} \times G_{\text{geiger-eff.}}(\lambda)$$

$\text{QE}_{\text{internal}}$ : essentially 100 %

$T(\lambda)$ : strongly varies with  $\lambda$ , could reach 80-90 %

$A_{\text{active area}}$ : some number between 20-80 %

$G_{\text{geiger-eff.}}(\lambda)$ : strong function of applied  $\Delta U/U$ , for  $\Delta U/U \geq 12-15$  % could become  $\geq 95$  %

# Geiger Efficiency $G_{\text{geiger-eff.}}(\lambda)$

High Geiger efficiency can be achieved for high  
Over-voltage  $\Delta U/U$ :  
Relative overvoltage  $\Delta U/U \approx 12 - 15 \%$

# Reflectivity of Si

FIG. 19. Near normal reflectance spectra in the wavelength range 0.3–1.1  $\mu\text{m}$  of silicon measured in the absolute spectrophotometer and the reflectance sphere. The reflectance sphere spectra consist of a corrected spectrum, R-sph, and the direct ratio between sample and reference signals, R-sph (quot.).

- Reflectivity of Si varies  $\sim 60 - 31 \%$  for 300 – 1000 nm at normal incidence.
- antireflective coatings can help
- Proper choice of window coating can provide efficiency  $\geq 80-90 \%$

# Reminder: light absorption in Si

Beaune99: Depleted CCD—5  
Don Groom 1999 June 24

This is the most important transparency I will show!

For the long wavelength end, temperature is important

Astronomical CCD's operate near  $-100^\circ$  C to achieve noise-limited performance

Red curve is empirical; other curves are calculated from phenomenological fits by Rajkanan *et al.*

- While 1000nm light can penetrate  $\sim 100$  μm deep into Si, light of 300 nm can penetrate only 5-7 nm!
- It is a major challenge to collect produced charge carriers from the very surface of the sensor, providing blue – near UV sensitivity

# SiPM with X-talk suppression: World record of ultra-fast light sensors in amplitude resolution

# Why the light emission from Si avalanches is important

- First observation of the light emission from reversed-biased Si p-n junction in 1955 (Newman)
- Revived interest about the effect in recent years because of:
- Cross-talk in SiPMs (GAPD, MPPC, micro-channel APD,...) spoils the amplitude resolution
- The light emission is proportional to the number of  $e^-$  in the avalanche. This puts a limit to the maximum gain under which one can operate the SiPMs
- If no measures are taken against the cross-talk, then the F-factor is worse than in classical PMTs
- As a consequence one encounters major problems in self-trigger schemes when measuring very low light level signals

# Cross-Talk

# Light emission spectrum

Imagine a SiPM operating at a gain of  $10^6$ .

It will emit  $\sim 17$  (39) photons.

The total internal reflection angle in Si is  $\sim 16^\circ$ ,  $\rightarrow$  only light within 0.24 sr can leave the SiPM

(only  $0.24/4\pi = 0.02$ )

$\rightarrow$  Only  $\sim 2\%$  of produced light comes out

Wavelength range	450 – 1600 nm	< 1117 nm
This measurement	$3.86 \times 10^{-5}$ ph/e	$1.69 \times 10^{-5}$ ph/e
Lacaita, et al., 93		$2.9 \times 10^{-5}$ ph/e

# X-talk suppression is improving the performance

*Known ways to suppress X-talk:*

*a) trenches*

*b) 2nd junction for isolating the bulk from the active region*

*c) Radiation damage*

*d) Special coating*

*e) Ultra-thin SiPM: expected reduction by a very large number*

# 4+ Fold X-talk suppression pursued by MEPhI – MPP researchers

- Ways to suppress the X-talk:
  - Isolating trenches, total internal reflection: reduction 8-9 times; (intellectual property)
  - 2nd p-n junction for isolating the bulk from the active region: reduction 4-5 times; (intellectual property)
  - High-energy ion implantation: reduction  $\geq 2$ -times (Intellectual property)
  - Special absorbing coating of the chip:  $\geq 2$ -times (Intellectual property)
  - Ultra-thin SiPM: expected reduction by a very large number (intellectual property)

# Record high PDE (pulsed mode LED, 100B type SiPM, 1x1 mm<sup>2</sup>)

Measurements at MEPHI and  
at CERN (Y.Musienko)

Measurements at MEPHI and at MPI

All results are consistent within experimental errors

# Achieved $T^\circ$ dependence: 0.5 % / $^\circ\text{C}$

# Light Sensors for astro-particle physics

- The classical PMTs are continueing to strongly improve in performance;
- We shall not exclude a possible „quantum jump“ in QE to  $\sim 70\%$
- A modest level financial support may accelerate this effort
- The number and types of SiPM matrixes from different manufacturers is increasing, the parameters are steadily and really fast improving
- Sometime soon, in a time scale of 2-3 years, we should be able to buy Si-based matrixes from several manufacturers with complete readout. We could then assemble large coordinate-sensitive imaging cameras like a lego
